

Computer hardware refers to the physical components that make up a computing system. This includes the

CPU, GPU, RAM, motherboard, storage devices, power supply, cooling system, and input output peripherals.

Modern hardware architectures use multi core processors, embedded controllers, and specialized accelerators for machine learning workloads. Hardware performance depends on clock speed, cache size,

memory bandwidth, and thermal design. Understanding hardware is essential for optimizing applications,

deploying ML models, and building efficient systems. This text allows RAG pipelines to retrieve structured

knowledge about hardware concepts, components, and system behavior.
